A PROCESS FOR THE IN SITU EXTRACTION OF OIL FROM SHALE BEDS AND SIMILAR FORMATIONS

Applicant: F. Ljungström

Svenska Skifferolje Aktiebolaget, Orebro

The present invention refers to a way of extracting oil from shale rock and similar beds in situ by means of channels which cut through the shale strata, are supplied with heat for the heating of the shale bed, and which are separated from the outlet boreholes formed in the shale by means of shale rock sections in between. The object of the invention is to achieve an improvement of this established procedure, in particular with regard to the quality and composition of the extracted products, which is essentially obtained by embedding heating elements which are preferably heated electrically, in heating boreholes, and which have smaller cross sections than the cross sections of the boreholes and by introducing into the interspace between the channel wall and the heating element thus obtained a filling that transfers heat from the heating element and the shale and simultaneously counteracts or prevents, respectively, a flow of the oil products gasified from the shale in the direction towards and along the heating element.

The invention will be more thoroughly described below with reference to the modes of implementation as shown in examples illustrated in the enclosed figure, and other accompanying characteristics of the invention which will also be discussed.

Figure 1 illustrates a section through a part of shale bed, in which the arrangement of a heating element installed according to the invention for the accomplishment of the process is shown. A vertical section through a rock formation according to a modified design is shown in Figure 2, and a flat view of this latter design is in Figure 3.

In a shale bed, 2, vertical channels, 4 in Figure 1 and 9 in Figures 2 and 3, are drilled, in which heating elements are embedded. These can consist of coiled pipe 44 according to Figure 1, equipped with inlet 32 and outlet 36 for a hot medium, gas or steam, which then remains separated from the surroundings during its passage through the coiled pipe 44. The pipe 44 can in addition be designed as an electrical resistor and function both for the fluid conduction of the medium mentioned and for the development of heat accompanying an electric current. With the design according to Figure 2 an electric heating element 17 is used. After the heating element has been inserted the channels are filled with backing sand a maleable substance, respectively, such as cement, clay or other suitable filler. The channels can be closed at the upper ends by collars 21, 28 which must necessarily be cemented into the rock foundation. On top of the shale bed 2 there is often an overlying stratum of lime 47 (Figure 2) with a thickness of several meters. Then the electrical resistance is only active within that portion of hole 9, which is surrounded by the oil-bearing shale. In other words, the electric current at the level of the lime laver is conducted through low resistance wires and therefore thermoelectric heat is not developed here to an appreciable extent.

Besides the channels mentioned above, exhaust holes $\underline{8}$ according to Figures 2 and 3 are made in the shale bed, through which the

products formed during the dry distillation [carbonization] are evacuated, and which consequently do not contain any heating element. These exhaust holes 8, which are sealed from the limestone at the top by collar 27, are connected through ducts 52 to a condenser which is best cooled by either air or cooling water.

At the surface expanse of the shale bed, channels 9 and 8, respectively, are arranged in such a way, as exemplified in Figure 3, that a heat-supplying channel 9 is surrounded by a number of exhaust holes 8. It is particularly advantageous to carry out the heating of the shale bed so that a wave of heat is transmitted horizontally through the shale bed, for example in the direction from the line of holes 40 in Figure 3 towards the line of holes 41 through a successive connection of the heating elements. "When this heat wave in part of the shale bed reaches a temperature of about 300°C, or prior to this, the shale begins to release combustible gases which in part are condensable and in part not condensable and which are conveyed to a condenser, common to a plurality of channels 8 which separates the former from the latter." The incondensable gases can be used, for example, for the preheating and heating, respectively, of a new zone of the shale bed with an arrangement as depicted in Figure 1. The duration of the degasification periods may be adjusted to the desired degree, by such variables as the distance between the holes, which can be, for example, 1/2 to 2 meters. The maximum temperature of the mentioned heat wave can amount to approximately 500°.

The hydrocarbons formed during the distillation process in the shale rock include condensable products from the lighest petroleum [gasoline] to the heaviest oil. Because the heating channels according to the invention are filled, the result is that the hydrocarbons are driven in the direction of the outlet channels 8, and thus away from the hot heating elements. Otherwise, of course, the hydrocarbons would find their way to these elements to a large extent, especially in the lower part of the shale layer because of the high rock pressure prevailing there. The extraordinary

advantage is thus gained that an unwanted cracking of the oil products is essentially avoided. The heating method according to the invention therefore allows recovery of a considerably greater percentage of high-grade gasoline products than with presently familiar methods.

While a shale bed section is being supplied with heat, an expansion of the shale sets in, at least in the beginning, in the longitudinal direction of the heat supply channels, and thus in such a direction as to cross the shale layers. If a number of such channels are simultaneously heated then these create within the shale mass static pillars of heat with a greater height than that of the colder shale mass located in between them. This shale mass therefore becomes affected by forces directed in a vertical direction, the effect of which is to separate the different strata of shale from one another, so that the combined vertical displacement of these plus the gaps formed between the strata of shale approach a configuration that corresponds to the shale layer at its highest temperature around the heated channels. In a cross section the shale layer assumes the appearance shown schematically in Figure 2. the other hand the shale layer within zones 54 limited by the dotted lines 53 in Figure 3 of the shale mass shows a falling temperature from the holes $\underline{9}$ to the holes $\underline{8}$, and within the resulting temperature differences the degasification can be considered to continue at different temperatures, for example from 300° to 500°. A certain molecule which is released from the shale mass at point 39 during the dry distillation process will on its way from this point to the outlet hole 8 pass through temperature zones of lower temperatures than that existing at point 39.

The pipe system shown in Figure 1 can be used for different heating purposes by allowing the existing channel in a previously degassed hot zone of the shale bed to conduct a fluid stream by means of pipes laid on the ground. Air, water, steam or other fluids which are heated in the process may then be led to a channel in a shale bed zone where the oil extraction is to be started or is already in progress.

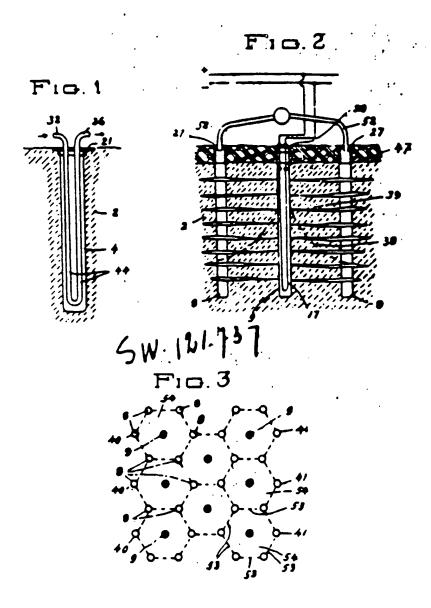

After the rock mass has been degassed, it wholly or partially consists of what is called shale coke, which indicates that after the gases are driven off, combustible carbon remains in the shale. According to the invention the rock mass can be ignited before or after cooling and the residual shale coke can be oxidized to shale ashes by introducing combustion air to the existing channel system. A very slow combustion that persists for several years can in this manner remain in progress, and the heat thereby generated can be utilized for various purposes, such as the heating of shale rock and hot water for homes, steam production, cultivation of plants, etc. According to the invention the cultivation of plants can also be carried out directly on the shale rock and in this way utilize the heat stored in the rock for a great many years.

Patent claims:

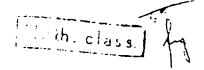

- 1. A process for in situ recovery of oil from shale beds and similar rock layers by means of channels that penetrate the shale strata, and are supplied with heat for the heating of the shale mass and which are separated from the exhaust holes formed in the shale by means of shale bed sections in between, characterized by heating elements being embedded in the heating channels, which are preferably heated electrically, and which have smaller cross sections than the cross sections of these channels, such that the interspace thus obtained between the channel wall and the heating element may be provided with backing sand that transfers heat from the heating element to the shale and simultaneously counteracts or prevents, respectively, the flow of oil products gasified from the shale in the direction towards and along the heating elements.
- 2. A process according to claim 1, characterized by the interspace being filled with a cast compound.
- 3. A process according to claims 1 or 2, characterized by the fact that a heating element in the form of a pipeline is brought

down into the heating channels, and the inner part of the pipeline, through which is led a hot medium, is entirely separated from the channel and that the heat supply to the pipeline is also produced electrically.

- 4. A process according to one of the previous claims, characterized by the fact that the channel system made in the shale bed is utilized for regenerative heating of the rock mass in which channels in a previously degassed hot zone of the shale bed are connected with pipelines over the ground and are allowed to conduct a medium which is heated in this zone, and also characterized by the fact that channels in an untreated zone of the shale rock are directly or indirectly supplied with energy utilized in this manner from the previously mentioned zone.
- 5. A process according to one of the previous claims, characterized by the shale coke remaining in the shale rock after the degasification is combusted to produce shale ashes by introducing air into the available system of channels.

Hartill on ritning.

SVENSKA SKIFFEROLJE AKTIEBOLAGET, ÖREBRO. Sätt att utvinna olja ur skifferberg och dylikt in situ.

Uppfinnare: F. Ljungstrom

Föreliggande uppfinning hänför sig till ett sätt att utvinna olja ur skifferberg och dylikt in situ medelst skifferlagren skarande kanaler, vilka tillföras värme för uppvärmning av skiffermassan och vilka äro skilda från i skiffern utformade ayloppskanaler medelst mellanliggande partier av skifferberget Uppfinningen avser att åstadkomma en förbatt- i ring av denna kånda metod speciellt i avseende på de utvunna produkternas beskaffenhet och sammansättning, vilket vasentligen ernås darigenom, att i uppvårmningskanalerna nedföras varmeelement, vilka företrädesvis uppvarmak på elektrisk våg, och vilka hava mindre tvärsektionsarea an dessa kanaders tvärsektionsarea och att i det så erhållna mel-Laurummet mellan kanalväggen och värmeelementet anbringas en tyllmassa, som förmedlar varmeövergång mellan värmeelementet och , skiffern och samtidigt motverkar resp. forhindrar en strömning av de ur skiffern forgasade oljeprodukterna i riktning mot och langs utmed varmeelementet.

Uppfinningen skall nedan närmare beskrivas under hänvisning till å bifogade ritning som exempel visade utföringsformer av densamma, varvid även andra uppfinningen kännetecknande egenskaper skola angivas.

I fig. I visas en sektion genom ett parti av ett skifterberg, i vilket är anbragt ett för sättets genomförande enligt uppfinningen anordnat varmeelement. I fig. 2 visas en vertikalsektion genom ett bergparti enligt en modifierad utföringsform och fig. 3 en planvy av denna senare utföringsform.

1 ett skifferberg 2 äro nedborrade vertikala kanaler, i fig. 1 betecknade med 4 och i fig. 2 och 3 med 9, i vilka värmeelement anbringas. Dessa kunna utgöras av en rörslinga 44 entigt fig. 1, försødd med intag 32 och avlopp 36 for ett hett medium, gas eller ånga, som darvid under sm passage genom rörslingan 44 ar skilt från omgivningen. Röret 44 kan därjamte vara utformat som elektriskt motstånd och fungera såval för genomströmning av del nämnda mediet som för överbringande av värme genom elektrisk ström. Vid utforingsformen enligt tig. 2 anvandes ett elektriskt

vårmeelement 17. Sedan varmeelementet nedförts, utfyllas kanalerna med en massa resp. gjutmassa, sasom cement, iera eller dytikt. Kanalerna kunna upptill vara tillslutna ry lock 21, 28, som lämpligen cementeras fast i berggrunden. Ovanpa skifferberget 2 a. otta överlagrat ett kalklager 47 (tig. 2° med en mäktighet av många meter, varvid det elektriska motstandet endast ar verksamt mom den del av håten 9, som ar omgivea av den oljeforande skiffern. Den elektriska sittemmen tillfores alltså motstandet genom lediningar, som i niva med kalklagret ana godo ledare och darfor har icke avgiva varme i mämmvård utstrackning.

Förutom de ovannaminda kuraferna upptagas kanaler 8 enligt fig 2 och 3 i statterherget, genom vilka de vid förrdestillationen aktrade produkterna avledas och vilka alltsa icke inrymma nagon uppvarmingssmordning. Dessa kanaler 8, som upptab aca (il), slutna av lock 27, sta genom ledanigar 52 i förbindelse med en kondensor, vilken lannsligen kan vara luttkyld eller också kyld av kylvatten.

I ytutsträckningen av det skitte berg, som skull avverkas, anbringas kaintei ir fesii. 8 t. ex. på sått, som framgår by (ig. 3. da) en varmelilltorselkanal 9 onigives av ett antaavloppskanaler 8. Det ar sårskilt fordelaktigt att genomföra skifferbergets uppvarmning sa. att en våg av varme horisontellt fortplantas genom skifferberget, t. ex. i riktning fran halcaden 40 i fig. 3 mot halvaden 11 genom suc- 7 cessiv inkoppling av varmeelementen. Nardenna vármevág i ett parti av skifterberget natt en temperatur av omkring 300° effer tid)gare, borjar skittern avgiva braumbara gaser, som dels aro kondenserbara dels okondenserbara och som inledas i en för ett flectal kanaler 8 gemensam kondensor, som avskiljer de torra fran de senare De okondenserbata gaser na kunna f, ex anyandas for for- (esp appvarmning av en ny zon av skifterberget vid utföringsformen enligt fig. 1. Avgasningsperiodens tulslangd varieras i onskad grad, ht, a. sammanhangande med det mellan hålen valda avstandet, som t. ev. kan varn - , a 2

4.

meter. Den namnda värmevägens maximitemperatur kan uppga till omkring 500

De vid destillationsprocessen i skifferberget bildade kolvatena omfatta kondenserbara produkter från den lättaste bensinen till den tyngsta oljan, Genom att uppvärmningskanalerna nu enligt uppfinningen åro igenfylldaernas, att kolvätena föras i riktning mot av-Toppskamderna 8, d. v. s. hort fran de heta uppvärmningselementen. Eljest skulle nämligen kolvätena i stor utstrackning söka sin vag till dessa element, speciellt i den nedre delen av skifterlagret till töljd av det där rådande höga bergtrycket. Man vinner sålnuda den utomordentliga fördelen, att en ickeonskvard spaltning eller krackning av olje produkterna vasentligen undvikes. Uppvarmningsmetoden enligt uppfinningen medgiver darför en utvinning av procentuellt väsenlligt mera högvardiga bensinprodukter än vid hittills kanda metoder.

Under varmetittförseln till ett skifferbergparti inträder atminstone till att borja med en utvidgning av skittern i varmetillförselkanalernas längdriktning, vilken korsar skitterlagren. Om 🏝 antal dylika kanater samcidigt bliva foremál for uppvarmning, bilda dessa inom skiffermassan staende varmepelare med större höjdmatt an den mellan desamma belagua kallare skitfermassan. Denna skiffermassa blir ductor paverkad av i vertikalriktningen gaende krafter, som sträva att skiljade olika skifferlagien från varandia, så att dessas sammanlagda vertikala matt pius mellan skifferlagren uppkomna spatterna narmar sig det, som motsvarar skifferlagret vid dess högsta temperatur kring de uppvarındakanalerna. Skitterlagret far i sektion ett utseemle, som schematiskt visas i lig. 2. A andra sidan uppvisar skifferlagret inom de medstreckade finjerna 53 begransade zonerna 54. i fig. 3 av skiltermassan en fallande temperatur från halen 9 till hålen 8, och kan inom de darvid forekommande lemperaturdifterenserna av_sasaangen tankas tortga vid olika temperaturer t. ex. fran 300 - till 500 . En ves molekyl som vid punkten 39 under forr destillationsprocessen frigores ur skitfermassan, kommer på sin våg från denna punkt till avloppshålet 8 att passera temperaturzoner, som alla uppvisa lägre temperatur an den. som existerne vid punkten 39.

Det i fig. I visade ledningssystemet kan användas för olika uppvärmningsåndamal, genom att en i en redan avgasad het zon av skifferberget betintlig kanal bringas genom över jord lagda tedningar att genomströmmas av ett fluidum, t. ex. luft, vatten eller anga, som hårunder uppvärmes och sedan t. ex. ledes till en kanal i en skifferbergzon, där objeutvinning skall inledas resp. pågår.

Sedan bergmassin ovgasats, består den helt eller delvis in s. k. skifferkoks, d. v. s. gaserna åre gydrivna, men brannbart kol finnes annu kvar i skilfern. Enligt uppfinningen kan bergmassan Tore eller eller avsvalning antländas och skilferaska, genom inforande av förbranningsluft i det förefintliga kanulsystemet. En mycket langsam, under många ar pågaende förbranning kan på detta sätt förtga och det darvid biblade varmet utnyttjasför olika andamal, sasom uppvarmning avskilferberg, varmvalten till bostader,, angsälstring, vaxtodling e. d. Växtodling kan öven enligt uppfinningen med fördel anbringas direkt på skilferberget, som på så sätt under en lång följd av år kan tillgodogora sig det i berget magasinerade varmet.

Patentanepråk:

 Satt att atviuna olja ur skifterberg och dylikt in situ medelst skifferlagren skarande kanaler, vilka tillföras varme for uppvarmning av skillermassan och vilka avo skilda make as Transa sametina delst meltanliggande partier av skitterbergel. kannetecknat darax, all i uppyarmningskanaterna nedferas varmeetenient, vilka foretradesvis appyarmas på elektrisk vag, och vitka hava Jaindre tyhrseklionsarea an dessakanalers (varsektionsarea och alt) del sic erhailma inclaminment methor distribuggen och varmeelementet anbringas en ivttmassasom formedlar varioeover_{so}m_s mellan varioes elemental och skattern och suglidigt molverkar resp. forlundrar en strammig av de ur skillern forgasade oljeprodukterna i eddining
